A METHOD OF FORMING SYSTEM TO FORM A LAYERING OF

ELECTRONICALLY-INTERACTIVE MATERIAL

5 The object of this invention ~~patent~~ is a method ~~system~~ for the formation of a layering of electronically-interactive material, ~~according to the characteristics of main claim.~~

Technical Field

10 By the term electronically-interactive material, we mean any kind of material which is capable of electronically interacting both in an active sense, such as through conductivity, or in a negative sense, such as through insulation, and does not exclude other parameters such as the typical on/off function which characterizes ~~characterises~~ micro-processors.

15 The invention is used preferably, but not exclusively, for the formation of a layering of electronically-interactive material, such as in: the manufacture of electronic circuit boards; the creation of screens with a layer of electronically-interactive material to project images from a flat screen to create displays, which may also be flexible, directly incorporating a computerized ~~computerised~~ system which does not exclude the function of a microprocessor with both organic and non-organic material, including the function of intelligence which may or may not be artificial, similar to cerebral functions, and also visualization ~~visualisation~~ or non-visualization ~~non-visualisation~~ with different grades of variable luminosity materials by means of electronically induced phenomena which cover the entire range of the spectrum.

20

Background Art

According to the current state of the technology, the formation of a layering, either composed of a single layer or a number of layers, is carried out by either mechanical, chemical or photo-chemical methods. The techniques of layering with mechanical systems are slow and not very suitable for the miniaturization ~~miniaturisation~~—and precision which modern electronic techniques need to acquire.

For example, in order to create electronic circuit boards, which is one of the main, although not exclusive, uses of this invention, either photographic or photo-engraving techniques are used, ~~and~~ which are far superior to mechanical systems.

In spite of this, modern technology requires techniques which are more rapid and efficient, and which also have miniaturization ~~miniaturisation~~—and precision capacities superior to those achieved up until now, if possible.

It is well known that, even with photo-engraving techniques, since a photo-sensitive layer has to be engraved, it is not possible to create designs and miniaturized ~~miniaturised~~—circuits below a certain dimension. That is, it is not possible to go below certain values, which are determined by the minimum distance between two engravings, otherwise it would make the thin layer between them unstable because, if it is too thin, it could be easily detached or ruined. As a general rule, an acceptable value for the ratio of the distance between one engraving and another and the thickness of the layer is >1 . In fact, if the ~~said~~ ratio were less than 1, the height of the section of the layer would be

greater ~~than then~~ the width, so the risk of breakage and a resulting short circuit between two adjacent circuits would be high.

DE-19817530A discloses a process and device for the production of a thin-multilayer structure.

- 5 US-3661304 discloses a pressure impulse apparatus for initiating formation of fluid drops such as ink, in high speed printing, wherein the drops are selectively placed on a paper web, providing a primary liquid supply at a constant pressure and starting means for applying a ~~an~~ higher pressure impulse, ~~the said~~ starting means including an auxiliary liquid supply.

10 Aim of the invention

The aim of this invention is to overcome the aforementioned drawbacks and to allow a layer of electronically-interactive material to be rapidly and quickly formed on a surface, having ~~which has the~~ maximum precision even with the smallest of designs and ~~which has an~~ extremely low cost.

15 Explanation of the invention

The problem is overcome according to ~~the~~ characteristics described ~~in the main claim~~ below.

Advantages

- The advantages obtained with the present invention ~~this~~ solution are the following:

- Speed of the process.
- Maximum simplicity.
- Maximum precision.

- Maximum miniaturization ~~miniaturisation~~ of the structures designed and integrated in the layer.
 - Maximum reliability, safety, robustness and duration of the layering.
 - Overall reduction of manufacturing costs.
- 5 - Respect for the environment with the elimination of all waste materials or pollutants.

Brief Detailed description of an applicationthe drawings

These and other advantages will be shown in the following description and attached drawings of a preferential application of the solution according to
 10 the present invention, the details of which are intended to be exemplary an
example and not a limitation limiting.

Figure 1 is a schematic view of a the mechanical solution of an the
 application machine for the formation of a layering of electronically-interactive
 material on a support sub-layer, such as in the manufacturing of an electronic
 15 circuit board.

Figure 2 is a three-dimensional schematic view of a the feeding system
 of a the distribution unit for the material used for the formation of the ~~said~~
 layering of electronically-interactive material.

Figure 3 is a view of the distribution unit for the material used for the
 20 formation of the ~~said~~ layering of electronically-interactive material.

Figure 4 is a schematic front view of the various components of the
 distribution unit of the system according to the attached claims present
invention.

Figure 5 is a three-dimensional schematic view of a machine which embodies the system for the formation of a layering of electronically-interactive material; according to this invention.

Detailed description of the solution illustrated in the drawings

With reference to Figure 1, ~~it is clear from the characteristics in the claims that~~ the formation of the layer of electronically-interactive material is carried out according to an innovative technique compared with previous technology, as follows:

- A support (a board of plastic material S, for example) is positioned on a mobile bed 2, where the movement of the mobile bed 2 is controlled and programmed by a microprocessor according to a given co-ordinate (Y).

- Above, there is a distribution unit for punctiform jets of the liquefied material to be deposited (3) in order to form the ~~said~~ layer on the ~~said~~ support (S). The distribution unit is programmed to move transversally in a controlled manner by a microprocessor, similar to that of a traditional inkjet printer, with the ~~said~~ distributor having a number of nozzles for the distribution of points the equivalent of pixels, which are able to cover a certain area equal to $n \times d$, where "n" is the number of nozzles which are sprayed in line, and "d" is the distance along the line from one nozzle to another, with a layout, for example, along three lines alternately disposed, 1, 2, 3, for a length of 70mm.

- The forward progress of the underlying support is in steps of 70mm, up to the complete deposit on the surface of the support in question (S).

Figure 2 illustrates ~~a the~~ feeding system of the liquefied material (which may be ~~coloured~~ colored, for example, with conductive powder in suspension in the various containers with a respective electro-induced vibration mixer), which comes from a main container 4 with a cover 40 for loading-40.

5 This container has two tubes for the liquefied material: one is ~~a the~~ feed line 41 for feeding by means of a solenoid check valve 410 to a pressure equalizer ~~equaliser~~ and regulator 5 which will be described in detail in the successive-~~function~~ operation, and the other is a return line 71 from a recovery and recycling container of the same liquefied material 7, the function of which
10 will be described later.

In this description, the liquefied material means the ~~said~~ material used for the formation of the ~~said~~ layering of electronically-interactive material used to cover the ~~said~~ support or plate of plastic material "S".

From the bottom of the ~~said~~ pressure equalizer ~~equaliser~~ and regulator 5,
15 there is a pipe 53 which leads to the bottom of a buffer 6 with an upper air chamber "A". The liquid to be deposited settles in the lower part "L", where there are pipes which take it to a ~~the~~ nozzle chamber forming a the distribution means for point-type sprays (31) which forms the ~~said~~ distributor. The ~~said~~ buffer 6 is suitable, therefore, to contain the ~~said~~ liquefied electronically-
20 interactive material "L", while the upper air chamber "A" acts as a pressure compensator, that is, as a damper, ~~being~~ able to increase or reduce according to the emission and/or consumption of the liquefied material and, therefore,

increase or reduce the request for material from the intermediate pressure
equalizer equaliser and regulator container (5).

The ~~said~~ buffer 6 is positioned above and is joined to the distribution
means for point-type sprays (31). Also, the ~~said~~ pressure equalizer equaliser and
5 regulator 5 may move upwards and downwards parallel to the up and down
movement of the ~~said~~ distribution means for point-type sprays (31) and the ~~said~~
buffer 6 on guide carriages 52, ~~and~~. The pressure equalizer and regulator 5 may
also be finely regulated in height with respect to the height of the ~~said~~ buffer (6)
and the ~~said~~ distribution means for point-type sprays (31) so that it may regulate
10 the pressure to be either higher or lower according to ~~for~~ the difference in level
and according to the principle of communicating vessels, with the pressure
variation induced by impeding the principle of communicating vessels by means
of the presence of the ~~said~~ air chamber "A" in the ~~said~~ buffer 6. In this way, by
being able to regulate the pressure to be either higher or lower according to the
15 programmed value by means of ~~the~~ computer control with a micro-processor,
the highest functionality is achieved.

It thus becomes possible to comply to the following conditions according to the
program:

- i₂ start distribution at the start of the transversal movement according to "X"
- 20 with a distribution pressure p1;
- ii₂ vary the ~~said~~ pressure immediately afterwards to a ~~the~~ value p2, where $p2 < p1$, with repetition of the cycle for every transversal movement of distribution-
deposit "X"; and

iii, vary the distribution again to a value of p_3 , so that $p_3 > p_1$, for a cleaning operation of ~~the~~ filters where the ~~said~~ material passes, so as to carry out a maintenance cycle during a non-operational phase, that is, when material is not being deposited according to "i" or "ii".

5 According to Figure 4 which schematically illustrates the distribution unit 3, we can see that, at the side of the ~~said~~ distribution means for point-type sprays (31), on one side there is an ultra-violet light transmitter 34 which has the function of polymerizing ~~polymerising~~ the fluid distributed on the surface of the support material (S), with the liquid being distributed in a form to be
10 polymerized ~~polymerised~~ due to the action of ultra-violet rays, ~~and on~~. On the opposite side there is an ultra-sonic distance sensor 32 which detects the distance of the underlying support (S) from the depositing bed and transmits the respective data to the processor so that, according to the program, it brings it closer, takes it further away or holds it at the same distance.

15 There is also a television camera 33 to the side, to view the surface of the support zone subject to the deposit in question, both for ~~the~~ fine tuning by means of reference points according to a well known technique, and for checking the correct distribution, depositing, regularity of the covering, etc.

 According to Figure 5, we can see a three-dimensional schematic view of
20 a machine which includes all of this equipment in order to use the system ~~according to the characteristics in the claims~~. The machine has a base 1 which includes the electric and computerized ~~computerised~~ electronic system, with a control computer ~~therefore~~ therefor, and which also has the function of

supporting the mobile bed 2 which is movable longitudinally by means of worm screws 20, the rotation of which is controlled by the ~~said~~-computer. The support panel "S", such as an electronic circuit board (in plastic material, for example), on which the layer of electronically-interactive material is to be formed, is
5 placed on the ~~said~~-bed.

A further transversal worm screw 30, the rotation of which is controlled by the ~~said~~-computer, is positioned above the ~~said~~-mobile bed (2). This transversal screw 30 carries the ~~said~~-distribution unit 3 as described-3.

The system for feeding the liquefied material is connected laterally to the
10 ~~said~~-distribution unit (3).

The feeding system is carried out, as already stated, in a controlled way by means of the ~~said~~-three containers 4, 5 and 6 with their respective piping.

At the back, block 340 forms the ultra-violet ray generator which feeds the ~~said~~-ultra-violet ray transmitter 34.

15 Going back to the ~~said~~-main feed chamber 4 and cover 40, it must be made clear that it also has the return pipe 71 which comes from a lateral tank 7 fixed at the side of the mobile bed 2, in order to be covered during the washing phase of the ~~said~~-distribution means for point-type sprays (31) during the non-operational phase of washing the filter with a higher pressure-~~p2~~ p3.

20 In this case, the fluid which is fed for the washing phase, which is neither polluted or damaged, is recovered by the ~~said~~-tank from below the nozzles in the ~~said~~-distributor means for point-type sprays (31), and taken by means of the ~~said~~ pipe 71 to the ~~said~~-main container 4.

All three of the containers 4, 5 and 6 have a vibration unit inside to keep the liquid constantly in motion during the feeding operation, in order to keep the suspended substance, which is heavier than the liquid, uniformly distributed (eg. copper powder for the conductivity of the material, pigments for the insulating material, etc.)

The ultra-violet (UV) ray device 34 advantageously works at room temperature and, because it heats up, it is cooled down at the same time according to a controlled temperature by suitable equipment which is part of the machine. In this way, the polymerization ~~polymerisation~~ of the deposited material is carried out at room temperature without damaging the material or the support, and without compromising the functionality of the entire depositing unit (3).

The distribution nozzles for the material to be polymerized ~~polymerised~~ by means of the distribution unit for point-type sprays (31) are advantageously conformed to supply punctiform (pixel-by-pixel) sprays equal to 1 pixel at a time in logical ~~sucessione~~ succession.

There are one or more rows of distribution nozzles. More rows of nozzles or distributors may be foreseen in order to deposit different materials.

An example of different materials could be the following, for example:

- conductive material;
- insulating material; and
- covering or protective material.

A further advantage is that the system includes the

activation or shut-down of the ~~said~~—ultra-violet ray polymerization
~~polymerisation~~-device (34) in a controlled way to make the following possible:

- the direct polymerization ~~polymerisation~~ immediately after being deposited,
or

5 - to fix it.

Abstract

A machine controlled by a computer for depositing a liquefied electronically-interactive material on a sheet or support card, ~~which includes:~~ a base (1) to support ~~a~~ the mobile bed (2) which is moved longitudinally (Y) by ~~means of~~ a worm screw (20) whose movement is controlled by a computer, and ~~which supports for the support and fixes fixing of the said support sheet or card~~ "S" on which the layer of electronically-interactive material is to be formed; ~~a~~ A bridge above the ~~said base~~ has with a transversal shaft (30) which also has a worm screw and whose movement is also controlled by the ~~said computer, in~~ ~~which the~~ The transversal shaft (30) moves the ~~said~~ distribution unit for the electronically-interactive material to be deposited (3) in an orthogonal direction (X).
